# CivicResolve

Implementation status ? completed work and remaining work

Updated October 29, 2026

## Summary

The citizen reporting flow automatically classifies service sectors and captures incident location from device location or a map pin. Description entry is text-only. Earlier portal workflow, rendering, and usability improvements are included below.

## Completed

? Fixed the citizen dashboard Thymeleaf rendering error and added regression coverage.

? Connected citizen, officer, and administrator pages to live complaint data and workflows, including officer updates, assignment, status changes, escalation lifecycle, deletion, department summaries, and officer account creation.

? Replaced hardcoded sidebar counts with data-derived values and fixed long email overflow; improved landing hero sizing and footer text contrast.

? Removed service-sector selection from the citizen complaint form. Gemini classifies reports automatically; supported results are canonicalized and mapped to official departments, with deterministic keyword routing when AI is unavailable or invalid.

? Removed address/place search from the incident-location form. Citizens can use the current-location button, click or drag the map pin, or enter an address manually. Validated coordinates are stored with complaints; reverse address lookup remains available.

? Removed voice dictation and microphone controls. Complaint descriptions are entered as text.

? Disclosed OpenStreetMap location sharing and documented provider policies and secure-context requirements.

? Added coverage for AI fallback, no-sector complaint submission, coordinate persistence and validation, and report-page rendering. The complete Maven suite passed with 106 tests before the latest UI changes; tests were not rerun per request.

## Remaining work

? Production configuration: provide and verify deployment Gemini, database, SMTP, and/or Twilio credentials; validate provider quotas, failure handling, and delivery in the target environment.

? Map operations: choose a production tile/reverse-geocoding provider or confirm deployment use meets OpenStreetMap tile and Nominatim policies; public endpoints provide no application-specific service-level guarantee.

? Live browser validation: confirm HTTPS device-location permissions, map tile/reverse-lookup availability, and mobile behavior in the deployed environment.

? Persistent notifications remain out of scope: notification pages show complaint activity, but there is no durable notification delivery/history system.

? Review and tune keyword fallback routing using real civic reports and operational feedback; it is deterministic and not a substitute for configured AI classification.

Existing completion-report PDFs were preserved. This status report reflects the text-only complaint form.
